

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

ultimately the same individuals become rhombogens and thenceforth produce only infusoriform young. Certain Dicvemids were found to contain both vermiform and infusoriform young. E. Van Beneden's view, that the infusoriform is the male Dicyemid, was confirmed by a study of its structure and a comparison of this form with the male Orthonectid (Rhopalura). From the fact that deeply staining bodies resembling the granules of the urn of the infusoriform, and probably for that reason spermatozoa were found among the germ-cells of the infusorigen, it was inferred that the infusoriform young may arise from fertilized ova, and that the infusorigen may be an adaptation for accumulating the germ-cells around a central cell to which the spermatozoa are also attracted, possibly by chemotaxis. was regarded as probable that both the male (infusoriform) and female Dicyemid migrate into the kidneys of the young Octopus and there form colonies of nematogenic females before males are produced.

Notes on the Blind Fishes. C. H. EIGEN-MANN.

- 1. There is a color pattern common to all the species of the Amblyopsidæ. This pattern is due to the arrangement of the chromatophores along the connective tissue septa separating successive muscle seg-The result is a series of longitudinal stripes where the septa are bent on the surface and a series of zigzag cross streaks. This pattern is best marked in Chologaster agassizii, in which but little color is present. It is somewhat obscure Chologaster cornutus on account of the great development of pigment. It remains only as an arrangement of chromatophores in the blind members of the family where color is no longer present in sufficient quantity to be evident to the naked eye.
- 2. Chologaster agassizii, which has so far been known from the type only, was secured

through a grant from the Elizabeth Thompson Science fund. It is a species with well developed eyes living permanently in caves. Its eye is notably smaller than that of the other species of *Chologaster* which live in open waters. The retina is very much like that of *C. papilliferus*, with thinner pigment layer. The eyes of the species of *Chologaster* show the following measurements:

- C. papilliferus, 32 mm. long. Vertical diameter, .832 mm. Longitudinal, .880 mm.
- C. agassizii, 39 mm. long. Vertical diameter, .720 mm. Longitudinal, .800.
- C. cornutus, 32 mm. long. Vertical diameter, .960 mm. Longitudinal, 1.120.

Thickness of the retina of

- C. papilliferus, 29-34 mm. long, .122 mm., 55 mm. long, .162 mm.
- C. agassizii, 38 mm. long, .107 mm., 62 mm. long, .130 mm.
- C. cornutus 27 mm. long, .73 mm., 43 mm. long, .83 mm.
- 3. The blind fish from Missouri is of different origin from the blind fishes east of the Mississippi. The details of this part of the paper have appeared in Science.

Regeneration and Regulation in Hydra viridis. HERBERT W. RAND.

In a series of regeneration experiments upon Hydra viridis it was found that the polyps regenerate, on the average, fewer tentacles than are originally possessed. The more tentacles before regeneration the greater is the mean number after regeneration. Eight-tentacled Hydras showed the greatest reduction in the number of tentacles. Six-tentacled Hydras showed no reduction.

The average deviation from the mean was practically the same before and after regeneration. The average deviation from the mean after regeneration, and also the average deviation from the original number, was greater in the eight-tentacled groups and least in the six-tentacled.

The mean number of tentacles regenerated by whole six-tentacled *Hydras* was
